## ABSTRACT

Due to more severe finished product specifications, environmental constraints, need for competitiveness and more generally severity of operation, a greater focus has to be placed on the performance of all catalytic units.

The financial penalties associated with poor process unit operation far exceed all costs related to catalyst, and particularly the costs of contracted services such as offsite regeneration or maintenance related costs.

Various expert services and technologies are available from the Eurecat group of companies, in order to help the refineries and petrochemical plants to achieve their goals. In order to achieve best possible catalyst performance, key focus areas include the Reactor (handling operations) and the Catalyst itself (ex-situ services).

All such services can be offered individually, in a very flexible way, to suit the customer's requirements, each of them providing clear financial benefits. In the field of ex-situ activities (the Catalyst), main services include catalyst regeneration, preconditioning or recycling. On-site expert services (the Reactor) may include catalyst sampling, handling operations, including dense loading or reactor supervision or expertise services.

In order to further enhance the benefits to the catalytic plants, the Eurecat group also offers a global catalyst service, or the complete management of a reactor change-out, which include many of the individual activities mentioned earlier, together with the services of partner companies for all maintenance activities. Examples of such global catalyst services are given in this paper.

## **A INTRODUCTION**

Until the seventies, most catalysts used in the oil refining and petrochemical industries had a very simple life cycle: they were either used for one production cycle until exhaustion of their catalytic properties, or otherwise they were used for a few cycles, with some in-situ regeneration between cycles. Disposal in a more or less acceptable environmental way was the last step. Under those conditions, there was a rather limited need for off-site services.

More recently, the situation has changed drastically, as off-site regeneration of many catalysts has become widely accepted and preferred by the industry. This is due to a number of reasons, including safety and time considerations and better catalyst activity recovery.

Together with off-site regeneration, other services such as off-site presulfiding, other preconditioning processes and catalyst handling have become available to help the refiners manage their unit shutdowns and start-ups. Furthermore, spent catalyst disposal is evolving towards more environmentally acceptable recycling schemes.

The growth of catalyst services is the result of more severe catalyst requirements due to more stringent product specifications or performance needs. Handling activities are now also becoming critical to meet those needs, and dedicated technologies and reactor expertise are now available to assist the operator with its turnaround activities.

In addition, a unique concept is offered by Eurecat group : the complete management of a reactor change-out as a global catalyst service. At present, catalyst management has become a reality.

## **B CATALYST AGING PROCESS**

During a catalytic operation, various factors can cause a temporary or permanent aging of the catalyst. As an example, let us illustrate the case of hydroprocessing catalysts :

### **Deactivation**

Depending on the type of service and unit severity, the cycle length of a hydroprocessing unit is typically between 6 months to 4 years. In fixed bed units catalyst deactivation during the run is compensated by a progressive increase in bed temperature, up to a certain value dictated by metallurgical constraints or product qualities. The end-of-cycle is usually determined by a level of activity too low to meet product specifications, but it also can be due to a unit upset (high pressure drop, compressor failure, hydrogen shortage), or to a scheduled unit shutdown. This is confirmed by the carbon content on spent HDS catalysts before regeneration, as shown on *Figure 1*.

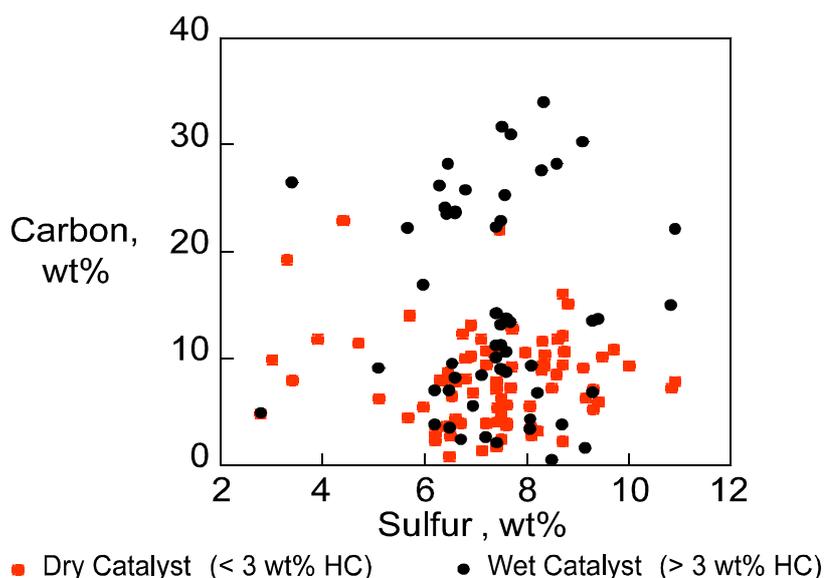

Figure 1 : Carbon & Sulfur on Spent HDS Catalyst

Deactivation is due to three main causes: carbon (or coke) laydown, active phase sintering, and metal poisoning. The detrimental effects of coke are a reduction of support porosity, leading to diffusional limitations, and blocked access to active sites. During off-site regeneration, good success is achieved with carbon elimination as well as active phase redispersion.

### Metal contamination

Metal contamination by nickel or vanadium is observed in units running with feedstocks such as VGO, atmospheric resids, or vacuum resids. The V/Ni weight ratio depends on the type of crude, and is usually in the range of 2:1 to 4:1. As nickel is not a poison for catalyst activity, being itself an active metal for hydroprocessing reactions, the criterion for reuse of a regenerated catalyst is generally based on the vanadium content.

Depending on the type of service, catalysts containing more than 2 to 4 wt% vanadium are usually considered unsuitable for regeneration and reuse.

Traces amounts of arsenic are found on some spent catalysts, and they remain on the catalyst after regeneration. It is generally observed that there is a very steep arsenic gradient from the top to the bottom of the bed under hydroprocessing conditions. Vacuum unloading of the top catalyst layers is advised to permit catalyst segregation and analysis whenever arsenic contamination is suspected. In most cases, when arsenic content exceed 1000 wt ppm on the catalyst, catalytic activity starts to be seriously affected.

Iron, sodium are other metal contaminants often found in the spent catalysts. Iron has a rather low catalyst deactivating effect and comes essentially from corrosion of upstream equipment, and is generally found in low quantities. Sodium is encountered in cases of unit upsets, such as desalter malfunctioning, contamination by caustic soda, or sea water heat exchanger leakage. Silicon contamination is also quite common for naphtha HDS units running on cooker naphtha, due to use of silicon-based anti-foaming agents, but it is increasingly found in diesel cuts as well.

## C OFF SITE CATALYST SERVICES

The availability of various catalyst services has gradually increased since the late 1970s, initiated by the rapid spread of off-site regeneration and pioneering attitude from Eurecat, offering alternative or new ways for refiners to more precisely evaluate catalyst aspects of their hydroprocessing or other process unit operation.

### Regeneration

Until the mid 1970s, all regenerations were conducted in-situ in the unit reactors, but off-site regeneration has gradually become the industry standard in the western world. Other parts of the world are rapidly increasing their use of off-site regeneration services. This technique is preferred to the in-situ regeneration for many reasons including safety, time considerations, and better activity recovery.

Different technologies are available in the industry to carry out off-site regeneration : rotating kiln, belt oven or fluidized bed oven. The *industrial regeneration process* most employed by Eurecat is based on the use of a *Roto-Louvre* oven technology, which enables an excellent contact between gas and solids (*Figure 2*). A high degree of homogeneity and excellent temperature control are achieved from the contact between hot air, passing through the spaces between the louvres, and the thin layer of catalyst rotating slowly inside this conical inner shell.

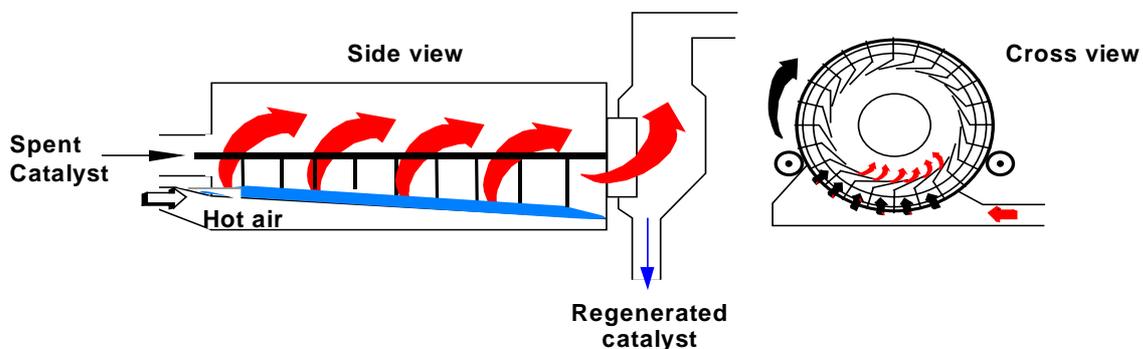

Figure 2 : Side & Cross view of a roto-louvre oven

*Catalyst quality and performance tests* are a critical part of all regeneration jobs performed by Eurecat in order to assess the regenerability or interest for reuse of a given lot of spent catalyst, and to ensure optimal quality control during the industrial process.

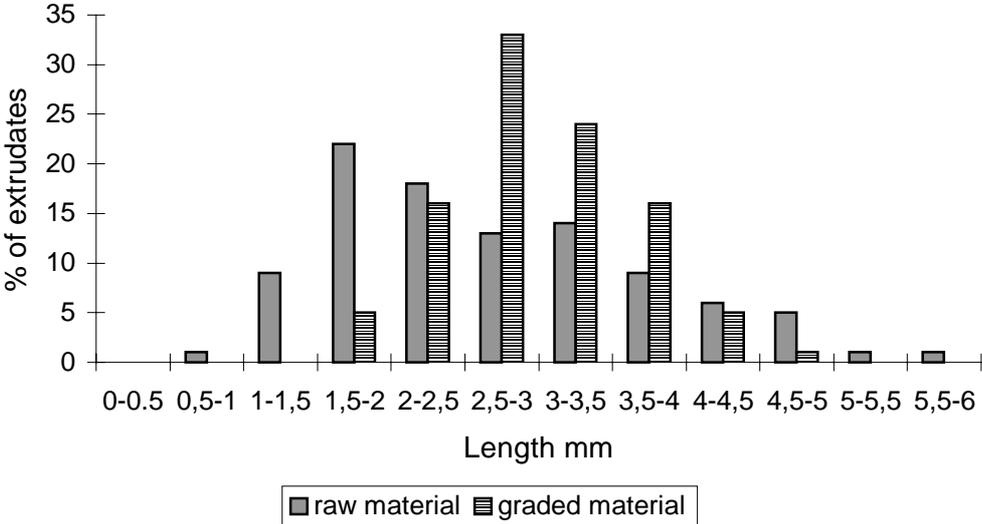

First, physical properties of the catalyst, such as mechanical strength (BCS or SPCS) and length distribution must be monitored. Comparing the surface area of the regenerated catalyst to that of the fresh catalyst provides an excellent indication of the catalyst’s quality. Carbon and sulfur analyses are also key factors and elemental metal analyses are necessary to identify metal contamination. The presence of metal contamination is not always linked with a loss in surface area.

Dynamic Oxygen Chemisorption (DOC) is a good complementary tool to evaluate active phase sintering for some special catalysts. Sensitivity to metal poisoning and the difficult analytical techniques involved in the DOC procedure require careful interpretation of the DOC test results.

The most reliable tool to evaluate the global performance of a hydroprocessing catalyst is clearly an activity test, and Eurecat has various equipment for that purpose.

**Catalyst Physical Separation**

Various *grading or physical separation equipment* are used by Eurecat to address all kinds of individual needs or situations : length grading, separation of components from catalyst mixtures, separation of ceramic balls of various sizes, etc. An example of *length grading* is shown in *Figure 3*: in this particular case, customer requirements were : average length > 2.6 mm ; less than 10% of extrudates < 2 mm.

*Figure 3 : Particle size distribution : raw and graded material*

## Presulfiding and other Preconditioning

In order to be “active”, all hydroprocessing catalysts containing molybdenum, nickel or cobalt must be sulfided. Thus, the metal oxides must be converted to the sulfided form.

Ten years ago, all sulfiding operations were carried out in-situ, i.e. after the fresh or regenerated catalyst had been loaded into the unit reactors. Various methods were used, the most efficient one being the use of a sulfur containing agent, such as dimethyl disulfide. Drawbacks to the in-situ method include: the handling of a toxic, environmentally unfriendly sulfur compound ; risk of non-homogeneous sulfiding; and the lost production time required for sulfiding.

Since 1986, Eurecat has pioneered the use of *Sulficat*, a new technology for off-site presulfiding (or presulfurization) of hydroprocessing and other catalysts. It provides the refiner with a stable non-toxic catalyst, homogeneously presulfided with each catalyst grain containing the correct amount of sulfur. This technique simplifies the unit start-up procedure and reduces start-up time considerably.

Innovation by Eurecat continues to take place with the introduction of *Totsucat*, a technology designed to provide complete catalyst activation off-site and to skin-passivate the catalyst as needed to allow its safe handling. As a result, the catalyst is ready for use, and the start-up procedure is reduced to a bare minimum, i.e., the heating of the unit to oil-in temperature.

Other preconditioning processes have been developed by Eurecat, that provide oil refiners and petrochemical plants some new options for the utilization of their catalysts, as shown on *Table 1*.

Table 1: Preconditioning Processes

Active Catalyst Phase	Application	Sulfiding	Reduction/ Sulfiding	Reduction	Chlorination
CoMo, NiMo	Hydrotreating	XX			
NiW	Hydrotreating	XX			
NiMo (CoMo) zeolite	Hydrocracking	XX			
NiW zeolite	Hydrocracking	XX			
Nickel	Hydrogenation		XX	XX	
Palladium	Hydrogenation			XX	
Platinum	Hydrogenation			XX	XX
Platinum	C <sub>5</sub> -C <sub>6</sub> isom			XX	XX
Platinum	Reforming		XX	XX	XX
Custom catalysts	Various	XX	XX	XX	XX

Eurecat is practicing commercially an off-site chlorination procedure (*Chloricat*), as part of a complete off-site regeneration procedure developed for platinum-based reforming catalysts. Excellent results are achieved in terms of platinum dispersion, as shown in *Table 2*.

Table 2: Platinum Dispersion of a Pt/Sn Reforming Catalyst

Catalyst	Fresh	In Operation	Spent	Chloricat Regenerated
Pt dispersion, %	91	100	47	97

### **Catalyst Resale**

Each individual refinery or unit determines its catalyst requirements and the most economical way to achieve them. As a consequence, refiners have from time to time surplus amounts of regenerable catalyst. Eurecat, through a catalyst resale program, assists refiners in finding an outlet for their material, and acts as a source point for those seeking to employ available regenerated catalyst.

### **Recycling**

Although landfilling is still widely practiced, increasingly restrictive environmental regulations regarding hazardous wastes and risks of future liabilities are inducing most refiners to turn to more environmentally sound options.

The non-availability of a “universal” recycling company, capable of handling all types of spent catalysts found in refineries and petrochemical plants, makes it sometimes difficult for the user to find the appropriate outlet for the spent materials. In addition, legislation and transportation regulations often vary between geographical regions and countries. The presence of many brokers or other intermediators does not always guarantee a safe and environmentally acceptable recycling process. Many plants prefer to deal with a well established company such as Eurecat which has, over the years, developed its own hydrometallurgical process, a unique expertise and a network of partner companies to assist the user in finding the optimal recycling solutions appropriate to his need.

Noble metal catalysts containing platinum (Pt) or palladium (Pd) are sent to specialized metal reclamation companies. For spent hydroprocessing catalysts, pyrometallurgy or a combination of hydrometallurgy and pyrometallurgy are available options.

### **Transportation and storage**

Regenerated catalyst can be transported or stored by means identical to those used for fresh catalyst, typically in drums, bins or bags.

Same as presulfided catalysts, spent catalysts are normally classified as self-heating substances ; therefore, drums or bins are required. Other national or regional restrictions for shipping may apply in various parts of the world.

Specialized bins from rental companies are now available, which provide a safe and efficient means to transport spent, regenerated, and presulfided catalyst. This mode of transportation is particularly attractive for turnaround operation, since the number of rental days is limited. In other cases, the cost of rental for a long period may be uneconomical.

## D ON SITE CATALYST SERVICES

During unit turnaround, catalyst handling takes place, together with various inspection, maintenance or other activities.

Such operations are very critical for the plant operators, in terms of quality of the work performed (unit performance after start-up), expenses (respect of the budget) and planning (respect of the schedule).

Following is a description of some of the critical services which can be outsourced by the refineries or petrochemical plants during their turnaround operations.

### Sampling

Before unloading the catalyst from the reactor, it is possible to take samples with the *Probacat* technology offered by Petroval (a company part of the Eurecat group). It is based on the use of a simple, robust, user-friendly vertical core sampler using a pneumatic device (with inert gas or compressed air).

It can be used to either determine a metals contamination vertical profile (example : *Figure 4*), or to identify preferential paths within the reactor bed. Sampling in drums or containers is also possible.

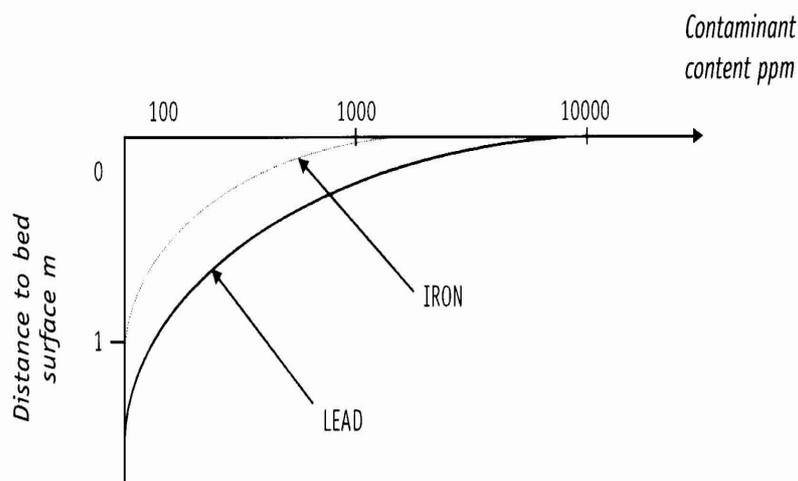

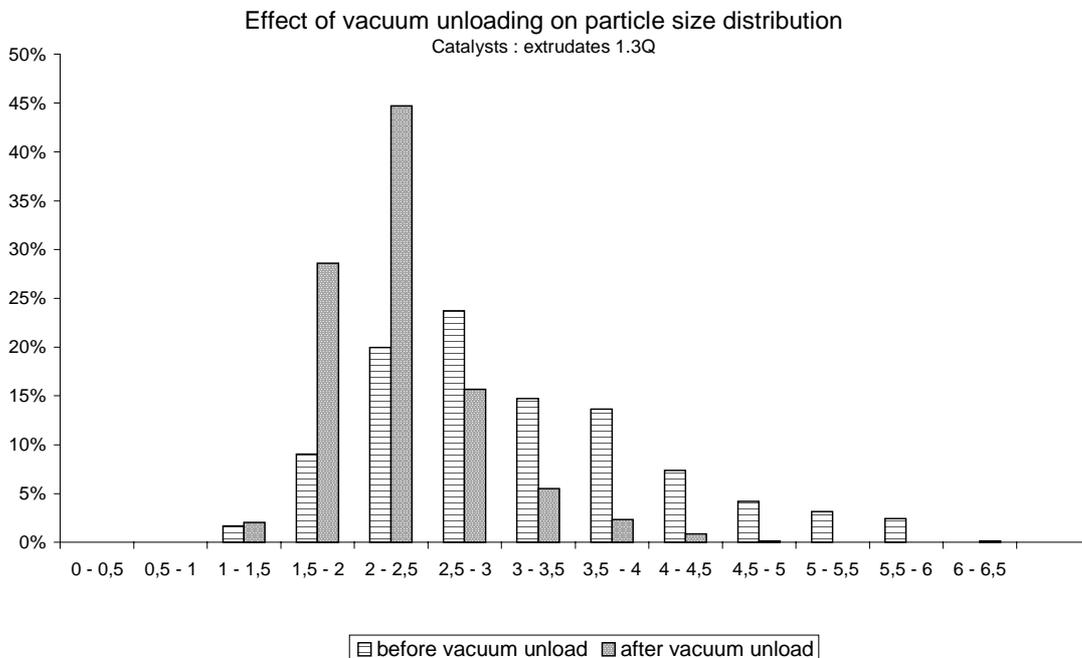

Figure 4 : Metals contamination profile

## Unloading

Spent catalysts due for unloading from a reactor are most of the time highly reactive materials, owing to their sulfided form. As such, they can react spontaneously when exposed to oxygen or air and require special handling, storage and transportation procedures. The presence of pyrophoric iron sulfide in spent catalyst, compounds the problem even more.

Various precautions, including unloading under inert atmosphere, either by gravity or by vacuum, are recommended by specialized handling service companies for safety reasons. Catalyst passivation methods also exist to render the spent catalyst less hazardous, but they exhibit various degrees of success. Special procedures have been developed to limit catalyst breakage during handling operations, insuring that a maximum of good quality catalyst will be returned to the refinery. Figure 5 shows typical catalyst breakage using vacuum unloading and inappropriate procedures.

	Before vacuum unload	After vacuum unload
Average length (mm)	2.86	2.02
Fines * content (% wt)	0.83	23.35
* fines are defined as catalyst particles which size is < 1mm		

Figure 5 : Typical catalyst breakage during vacuum unloading

Depending on the shutdown procedure used, the quantity of hydrocarbons adsorbed in the spent catalyst porosity may vary considerably. A film of hydrocarbons makes the catalyst less sensitive to oxidation, but this requires an additional stripping step prior to regeneration.

### Sock and dense loading

Catalyst loading is a critical factor for maximizing catalyst performance. Drums, bins or bags are-used, depending on the refiner's choice and safety considerations. Minimization of catalyst breakage and uniform catalyst distribution in the reactor are critical to the success of this operation. *Sock loading* may not maximize a reactor's capacity due to its tendency to create void spaces, and does not guarantee an homogeneous loading of the reactor which may give way to channeling and a non optimal use of the catalyst batch.

*Dense-loading* techniques are very popular to achieve an improved catalyst orientation and uniform void spacing, and also to maximize bed density (high activity and bed stability).

Among them, the most successful and reference for quality is Densicat<sup>®</sup>, the technology originally developed by TotalFinaElf and proposed by Petroval or its certified loading operators. The Densicat technology allows a predictable guaranteed maximum loading density, a perfectly homogenous loading, the highest speed and flexibility to accommodate many types of reactors, without any penalty due to higher pressure drops (*Figure 6*).

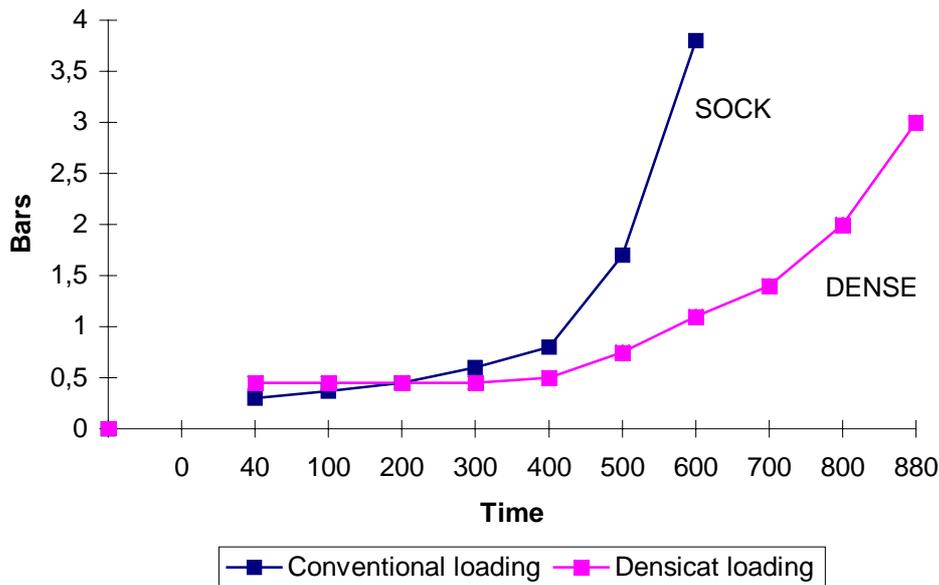

Figure 6 : Typical Pressure Drop Variation

The following example highlights the benefits of using Densicat<sup>®</sup> dense loading technology, in the following example case of a diesel HDS reactor:

- (a) a 1,5 % increase of catalyst quantity loaded compared to COP loading, with improved quality and lower SOR pressure drop (better catalyst bed homogeneity – no catalyst breakage).

(b) a 68 % reduction in loading time (13 hrs instead of 41 hrs) by using Petroval experts for Densicat®.

A comparison between Densicat® and other dense loading processes in terms of loading rate is shown on Figure 7. One can see for example that for reactors larger than 3,2 m diameter, Densicat® loading is 2 times faster than UOP's machine (1999 design), and 4 times faster than the COP loader. This is true as long as the handling organisation and facilities (crane, catalyst stored in large super sacks,...) can achieve the desirable throuput to feed the Densicat® dense loader. These data are based on actual feed-back from our customers.

Comparison of the loading rates m3/h - Densicat versus UOP-Cop-CATTECH

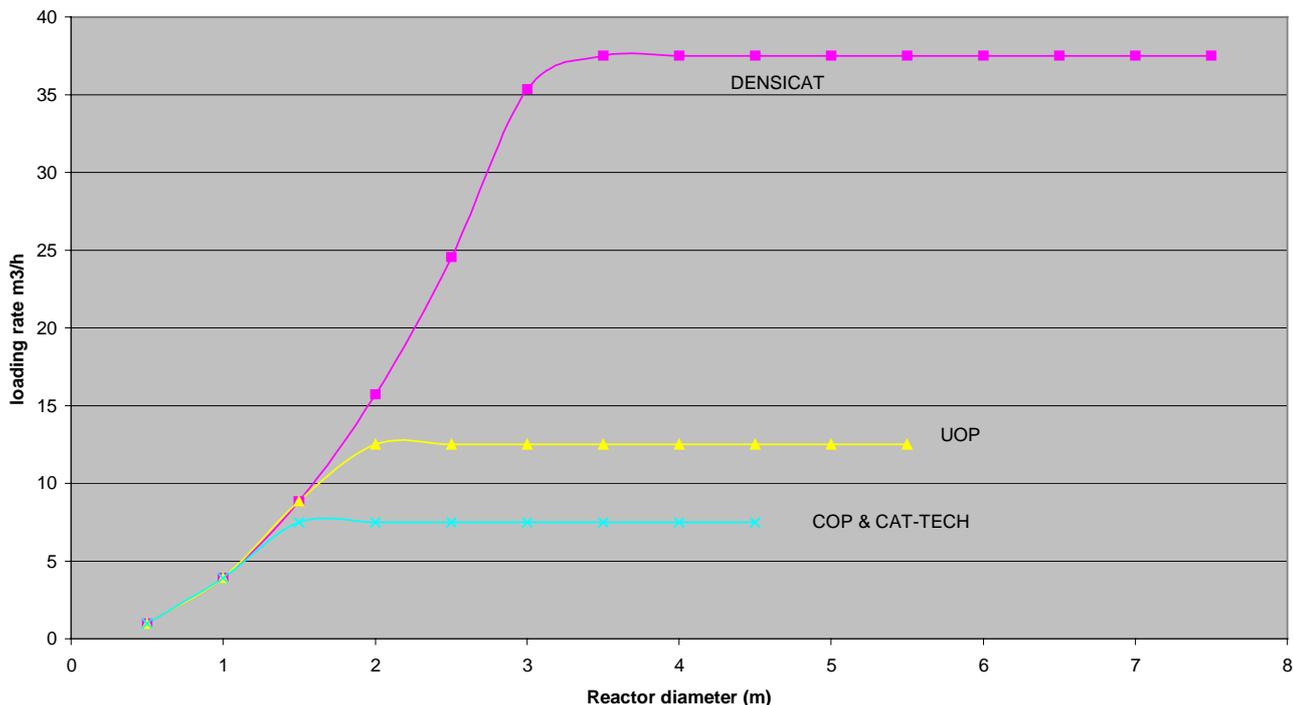

Figure 7 : Comparison of dense loading rates

Last but not least the expertise of the Petroval or Densicat® certified loading operators in terms of Quality and expertise are critical parameters when choosing a dense-loading technique : a predictable guaranteed loading density, a perfectly homogenous loading, no attrition, the highest possible speed and flexibility to accommodate many types of reactors.

### Supervision and Reactor Expertise

The best way that the plant's maintenance or shutdown crew has to insure that all catalyst and mechanical operations are successfully done with a quality work is to have an expert « right arm », independent from the contractor(s) who do the job. Such unique « reactor expertise » service, aiming at continuously monitoring the progress of the shutdown activities and the quality of the performed work, is offered by Petroval.

It also allows data collection from inside the reactors during the various phases (opening, unloading, loading).

This service is of particular importance in a new environment where shutdown operations are contracted to general purpose companies, not having necessarily the required knowledge about catalysts whereabouts. To-date, it has been very effective in obtaining successful turnaround operations for different oil companies all around the world.

## **E REACTOR MANAGEMENT SERVICES**

We observe very different philosophies in relation to the way refiners and petrochemical plants contract work during their unit shutdowns. However, a clear trend is the reduction of the number of main contractors and the multiplication of sub-contracts. The results of such move do not always prove successful.

In many industrial processes, a special care is needed for all shutdown operations linked to fixed bed or tubular catalytic reactors. However, plant personnel have more and more difficulties to do themselves all of the required control and monitoring, for various reasons: lack of personnel, expertise, non-availability round the clock,...

Eurecat group are offering various solutions to this problem:

1. As described earlier, by providing a team of expert personnel, employed by Petroval (a company affiliated with Eurecat) that supervise and monitor, on behalf of their client, all the work done by different contractors, and particularly the catalyst handling company in charge of unloading and loading activities.

Petroval's experience for supervision and expertise missions include units ranging from Catalytic Reformers, to Diesel or ARDS HDS units and to Hydrocrackers. Plant locations in Europe, North and Central America, Africa, Middle East and Far East.

Petroval, as a third party expert company, provide the best mean to insure quality control for reactor unloading and loading operation.

A typical example of this is a situation where Petroval were hired to audit and supervise an ARDS catalyst changeout (800 mtons of catalyst). The resulting time savings were 23% for the loading itself, and 14% for the whole turnaround, with an increased quality.

2. By providing a global service for reactor turnaround management. In this case, Eurecat are acting as main contractor for the operation, and they provide a complete set of services, from reactor shutdown to startup, including on site services such as catalyst sampling, unloading, inert entry, inspection, dense loading,... together with any required off site work such as catalyst regeneration or recycling.

Under the general coordination from a Eurecat specialist, all field supervision and specialized work such as dense loading is carried out by Petroval personnel, whereas partner companies are used for other mechanical, cleaning or catalyst handling tasks.

To-date, Eurecat's experience include both refineries and chemical plant in Europe, the most significant example being a complete management of 19 reactors from 5 process units during a major refinery shutdown, with personnel from 6 companies involved on site.

Typically, a very measurable benefit of such program is a 15% reduction of the turnaround time, because of better overall coordination, in addition to what we believe is the key: a complete quality insurance.

A major reason for the success of such approach is the optimal and synergetic use of various capabilities and expertise within the Eurecat group, as shown on Figure 8.

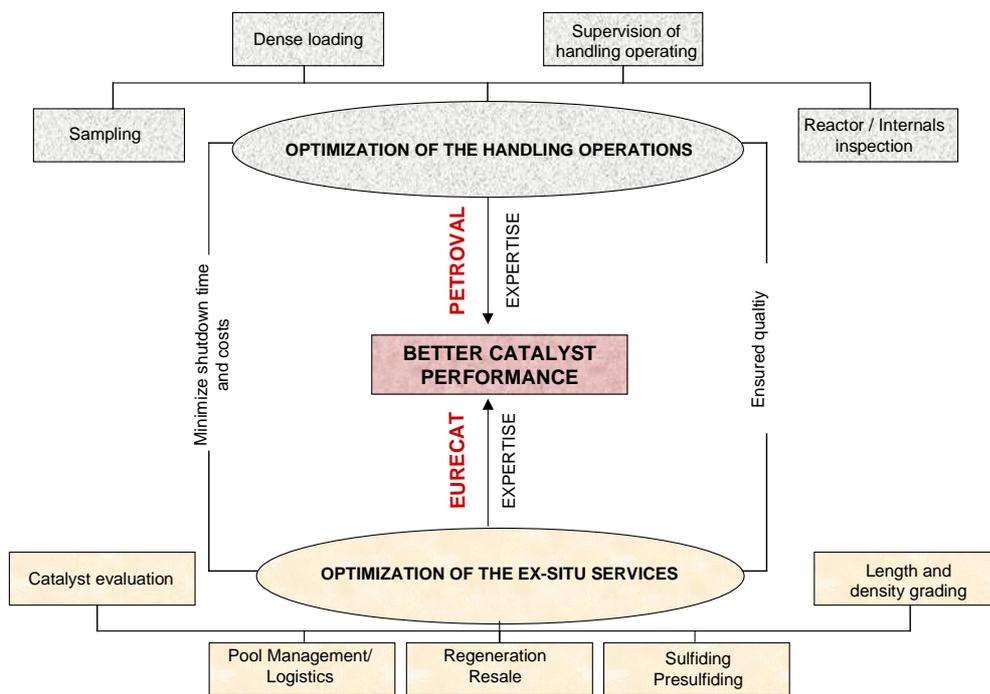

Figure 8 – Focus on Catalyst Performance

## **CONCLUSION**

The increased severity and economical constraints of many catalytic units operation put added demand on the catalyst performance. Such performance must therefore be monitored and optimized at all stages of the catalyst life cycle. Various off-site services are available to achieve these objectives, including regeneration, presulfiding and recycling.

On site services, and especially dense loading, or supervision and reactor expertise are also playing a key role to help the plant operators minimize the shut-down associated costs and to insure that they will get the best performance out of their catalysts and improve the overall economics of their units.

Eurecat group are proposing a unique concept, in terms of reactor management services, by focusing on all turnaround operation surrounding a catalytic reactor. Experience-to-date shows a tremendous positive response from our customers due to the benefits in terms of quality insurance and shutdown time savings.

Eurecat companies are able, to offer a wide range of the services required to achieve these goals, based on a proven practice of quality work, the necessary expertise and reliability of their people.
